Summary

- ERA-Interim driven simulations allow identifying ensemble bias and ensemble spread
 - Subtropical regions seem to be better simulated than tropical regions in terms of both model bias and uncertainty.
- The quality of RCM simulations over the SAM is not as good as that for Europe and North America.
- Some model biases are shared by different RCMs
- GCM-forced simulations:
 - Biases on the simulated temperature and precipitation patterns seem to be independent of boundary forcing.
 - Biases and uncertainties larger than for the ERA-I simulations (as expected).

Challenges for SAM

- Model improvements, particularly on the land-surface schemes
- Increasing resolution (22 km)
- Increasing the ensemble size
- Availability of reliable datasets of high-quality observations covering the whole South American continent
