Why a National Drought Observatory?

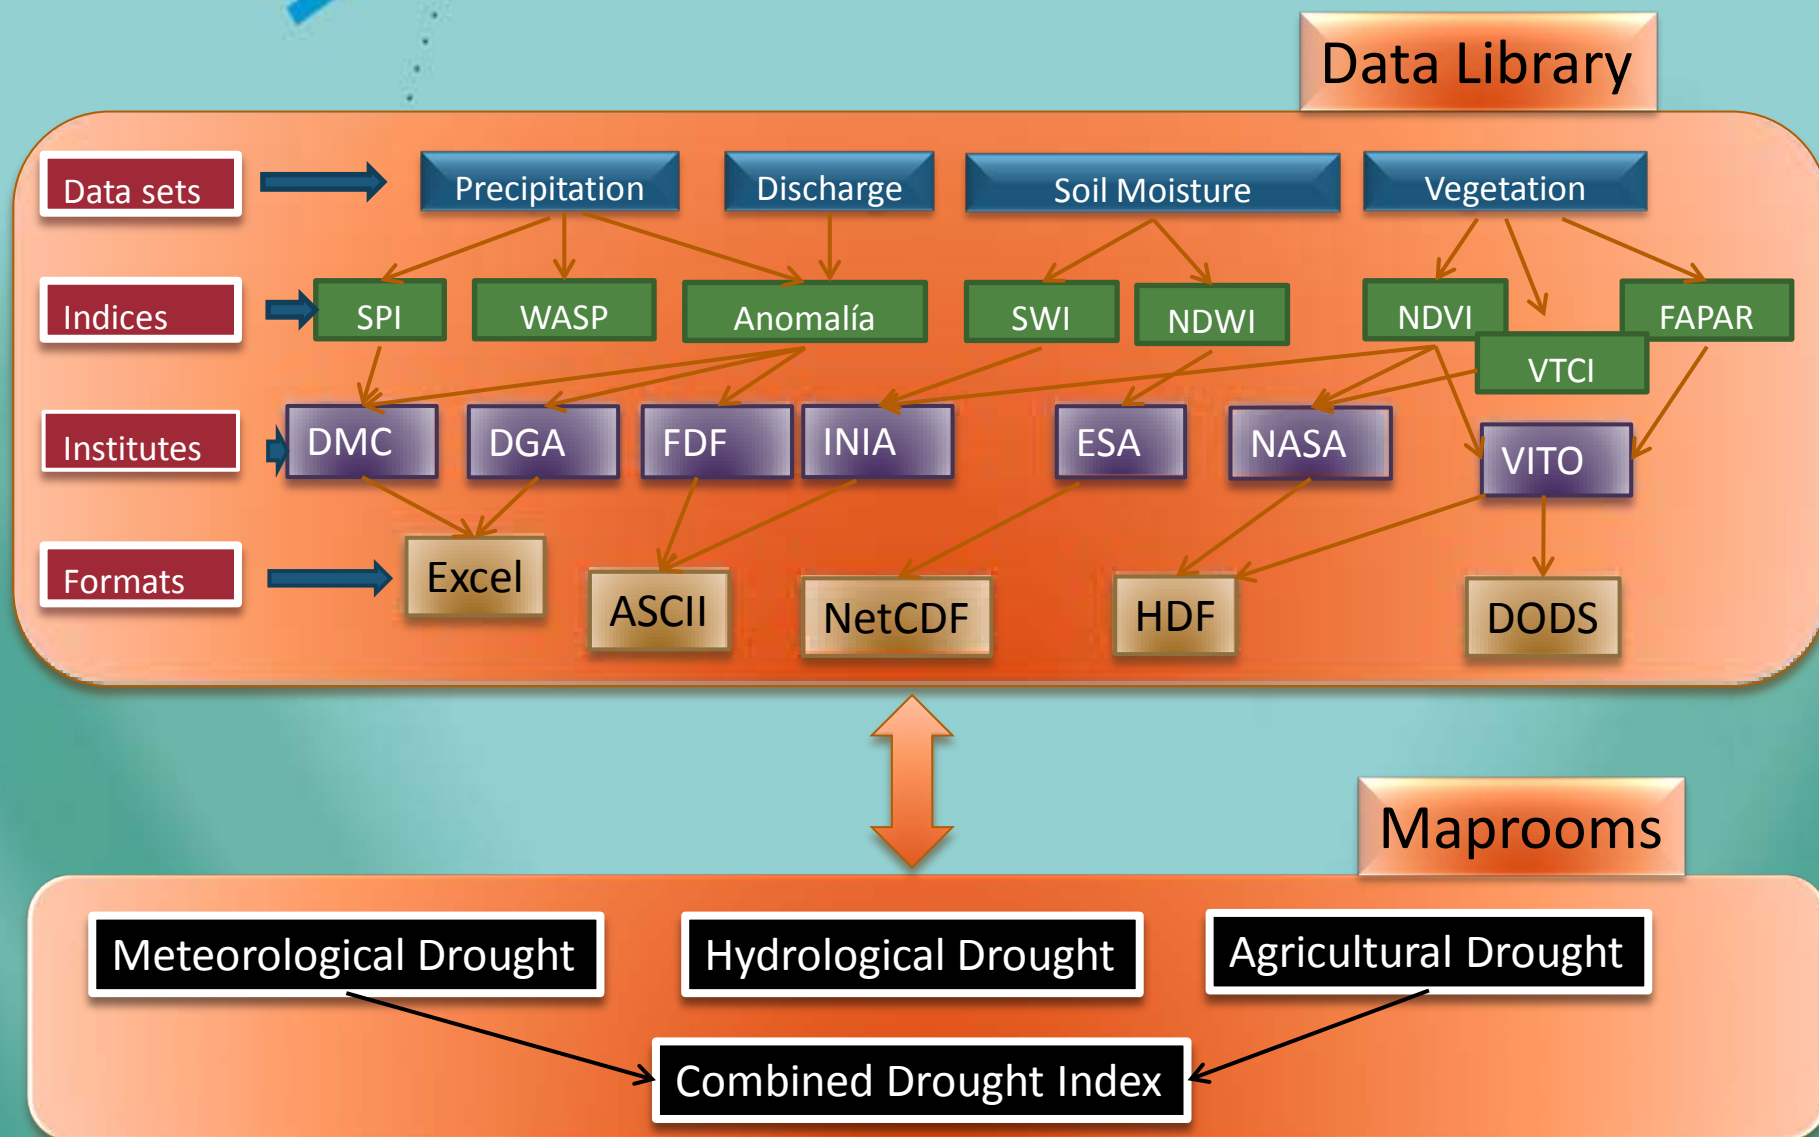

Objectives of the agroclimatic observatory

Requierements:

1. Count with all relevant agroclimatic information that:
 - are easy accessible
 - are up-to-date
 - consider different components of drought (meteorological, hydrological and agrí cultural)
2. Be based upon already available information from the different national partners and complement with additional **remote sensing data sources**
3. Allow identifying areas most affected by droughts to allow prioritizing actions
4. Count with a seasonal outlook, on the evolution of drought conditions
5. Count with an environment that allows devellopping new applications

Maprooms

- Visualization for end users
- portal / observatory

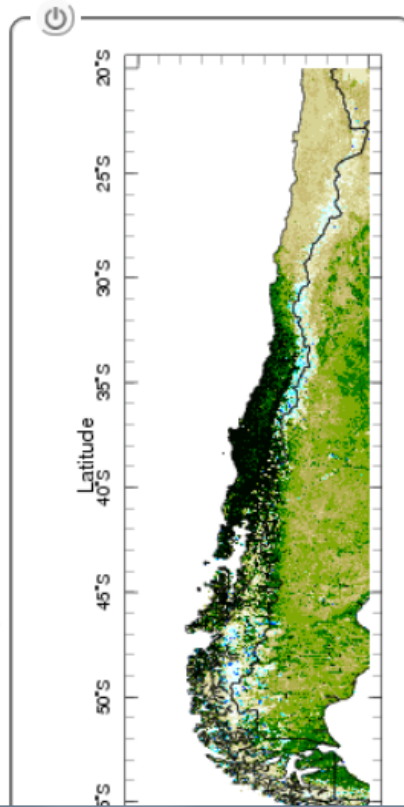

The screenshot shows the Maprooms web interface. At the top, there are logos for the Ministry of Agriculture, FAO, IRI, and CAZALAC. The main navigation bar includes 'Maproom', 'Monitoring', and 'Language' (set to 'english'). The 'Monitoring' section has dropdown menus for 'Region' (Chile), 'Variable' (NDVI), and 'Variable' (Observed). Below the navigation bar, there are tabs for 'Description', 'Dataset Documentation', 'Dataset', 'Contact Us', and 'Instructions'. The 'Description' tab is active, displaying the title 'Normalized Difference Vegetation Index' and a paragraph explaining that the images are derived from the MODIS sensor at 250m spatial resolution, provided every 16 days. It also mentions that the interface facilitates access to vegetation status from MODIS images provided by the United States Geological Survey. A second paragraph states that the interface allows users to select desired vegetation variables for a desired region using spatial averages, and refers to the instructions tab for help with customizing graphs. A third paragraph explains that NDVI is the ratio of two wavelengths, red and near-Infrared (NIR), and compares healthy and sparse areas of vegetation by examining their difference in wavelength absorption and reflection. It notes that healthy vegetation growth, such as forests, will absorb more and reflect less visible light (red wavelengths) compared to sparse vegetation. For example, an area of forest would yield a NDVI ratio closer to 1 compared to 0 for a desert. The predictive value of NDVI is attributed to its ability to integrate general biological growth over long periods of time. On the right side of the page, there is a map of Chile showing the Normalized Difference Vegetation Index (NDVI) data. The map is oriented vertically with latitude on the y-axis, ranging from 20°S to 50°S. The map shows a green color scale representing vegetation density, with a legend on the right side of the map.

Normalized Difference Vegetation Index

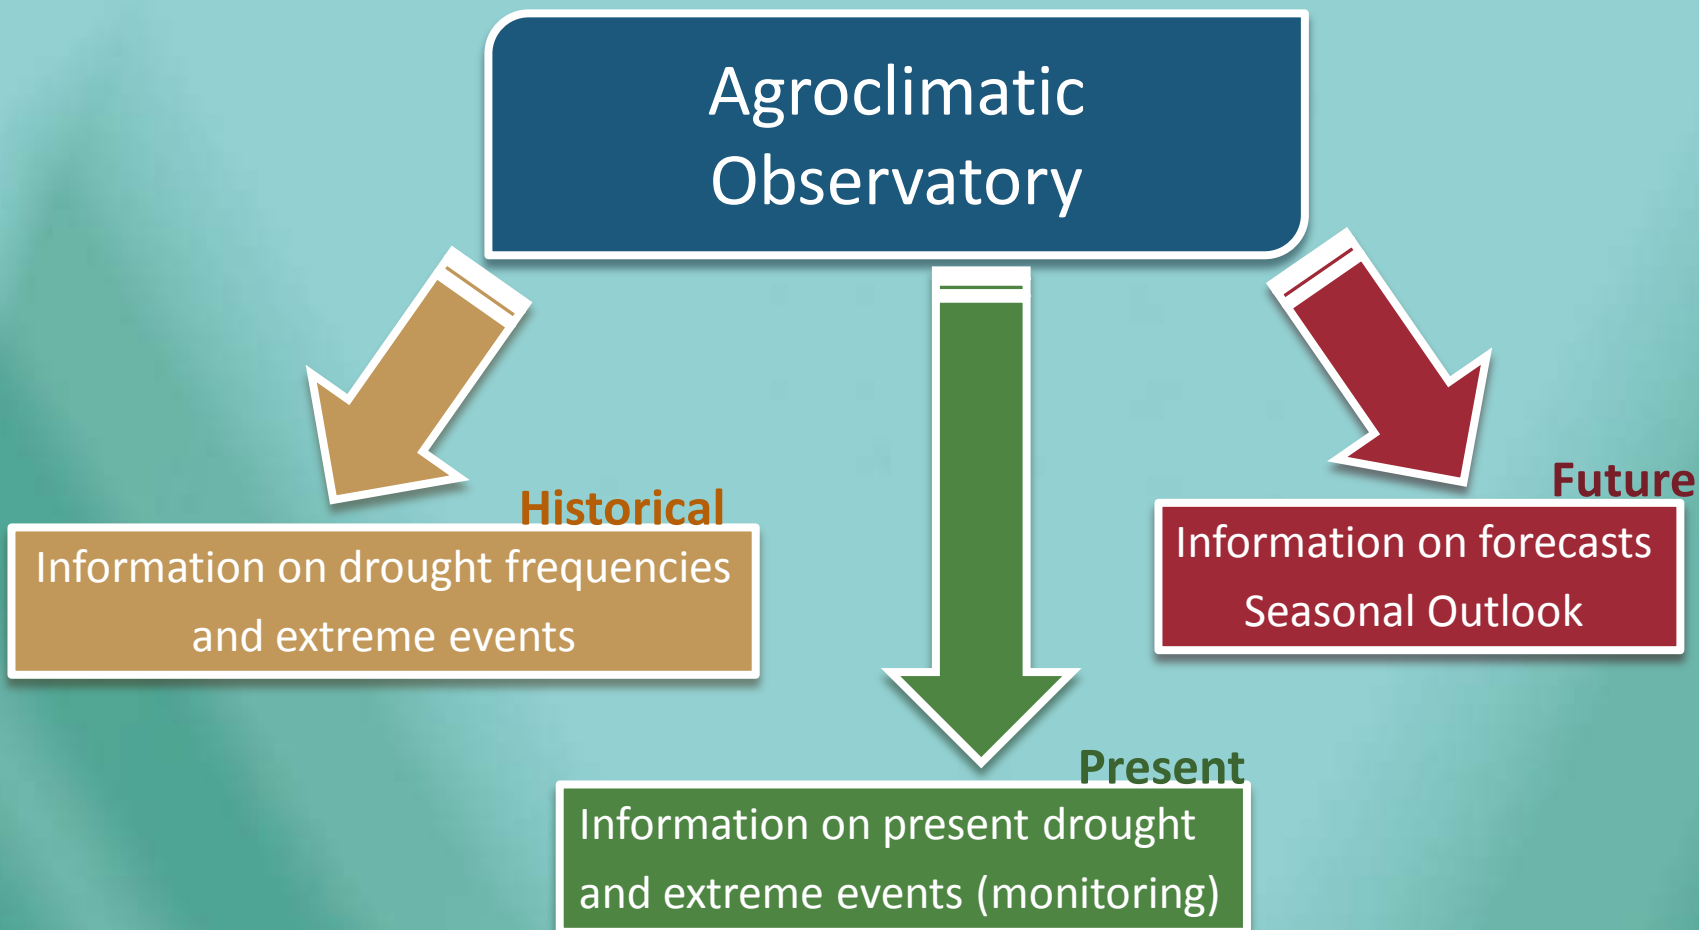

The images on this page are derived from The Moderate Resolution Imaging Spectroradiometer (MODIS) sensor at 250m spatial resolution provided every 16 days. This interface facilitates access to the vegetation status from MODIS images provided by the United States Geological Survey.

The interface allows users to select desired vegetation variables for a desired region using spatial averages. Refer to the instructions tab for help with customizing graphs.

NDVI: The Normalized Difference Vegetation Index (NDVI) is the ratio of two wavelengths, red and near-Infrared (NIR). The index compares healthy and sparse areas of vegetation by examining their difference in wavelength absorption and reflection. Healthy vegetation growth, such as forests, will absorb more and reflect less visible light (red wavelengths) compared to sparse vegetation. For example, an area of forest would yield a NDVI ratio closer to 1 compared to 0 for a desert. The predictive value of NDVI is attributed to its ability to integrate general biological growth over long periods of time.

Drought Monitor

The maproom is a collection of maps and other figures that monitor drought at present, near future and in the recent past. The maps and figures can be manipulated and are linked to the original data. Even if you are primarily interested in data rather than figures, this is a good place to see which datasets are particularly useful for monitoring current conditions.

Drought Monitor

A drought monitor showing relevant drought indicators.

Historical Drought Frequencies

Historical drought frequency analysis for Chile.

Forecasts

Climate forecasts can be relevant instruments to prepare for upcoming climate risks. In this maproom, the results from international forecasts as well as national tailored forecasts are shown.

Drought Return Periods

This map shows the return periods for droughts, expressed as a deficit compared to mean precipitation amounts, using a Regional Frequency Analysis using L-moments (RFA-LM).

The RFA-LM (Nunez et al., 2010) determines the frequency of drought events by pooling stations in climatologically homogeneous regions. This allows application of more robust statistics, especially in regions with limited datasets such as the drylands.

The L-moment-approach is an improvement over normal moment theory, as outliers and extreme events do not disproportionately influence distribution selection. As such, the RFA-LM method is the most appropriate method in regions with interannual variability and short record lengths. More information on the methodology of the RFA-LM can be found [here](#).

Standardized Precipitation Index

This map can be used to identify the intensity of drought or excess of rainfall for each month. It shows the Standardized Precipitation Index (SPI)

SPI values allow comparing deficit throughout Chile. The more severe the situation, the more negative the SPI value. The table below can be used to interpret the SPI value.

- Allows comparing deficit throughout Chile
- Allows evaluating the duration of the deficit

Range of the Standardized Precipitation Index

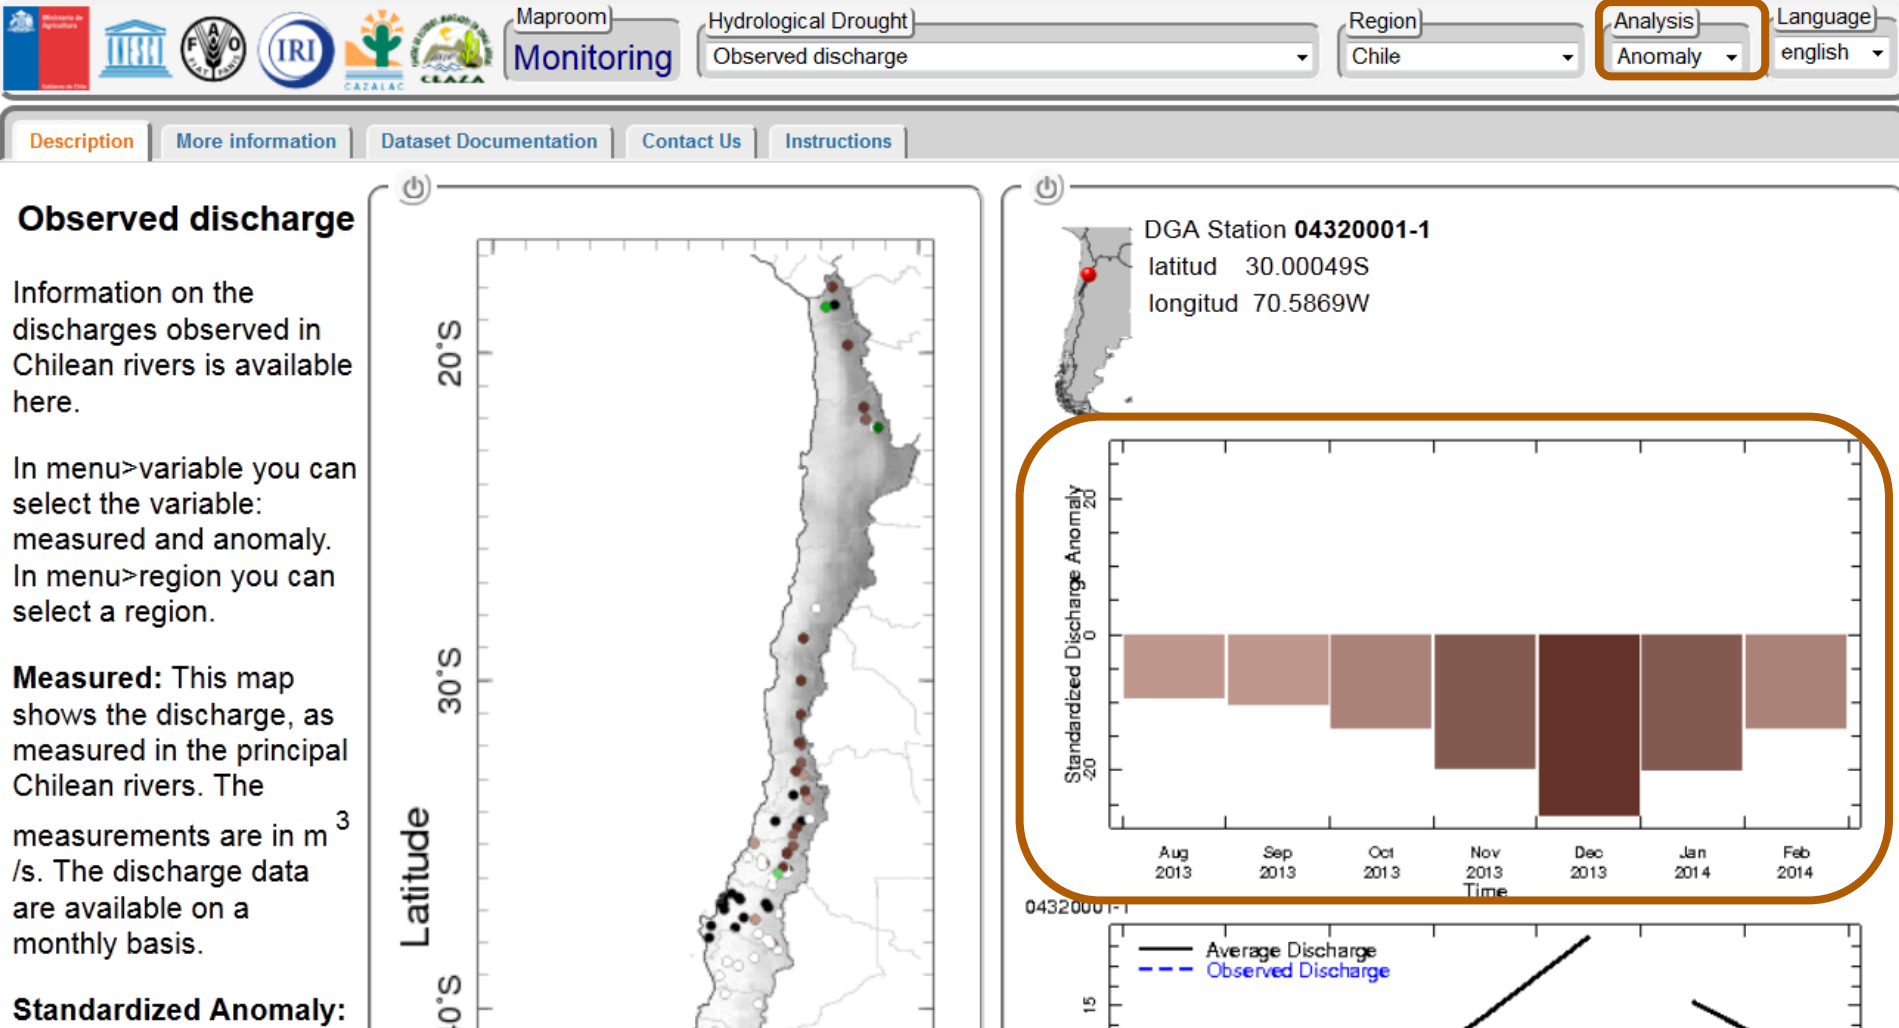

SPI ≥ 2.00	Extremely wet
$1.50 < \text{SPI} \leq 2.00$	Severely wet
$1.00 < \text{SPI} \leq 1.50$	Moderately wet
$-1.00 < \text{SPI} \leq 1.00$	Normal
$-1.50 < \text{SPI} \leq -1.00$	Moderately dry
$-2.00 < \text{SPI} \leq -1.50$	Severely dry
SPI ≤ -2.00	Extremely dry

4. Combined Drought Index

Combined Drought Index

Challenge 1

- **SPI-calculations** from station data are often inaccurate, due to limited station data and inadequate interpolation techniques
- **Remote sensing** datasets are too coarse to form a real alternative
- **Holistic Drought Indicators** that combine different aspects of drought are dependent on climatic conditions: poor performance in drylands.

- **Merging techniques** can provide partly solutions

Drought Early Warning

There is a close relation between drought and 'el Niño' (SST)

(Verbist, Robertson et al., JAMC, 2010)
